Conclusions

The Roberge-Weiss transition

Phase structure of QCD at imaginary chemical potential and generic number of flavors.

A case study: $N_f = 8$

Michele Andreoli

Pisa Univ. & INFN

28 September 2016

Lattice basics

A first principle non perturbative QCD formulation

$$S[\psi, \bar{\psi}, U] = \underbrace{-\beta_G \sum_P \frac{1}{3} \text{ReTr}[\prod_P U]}_{S_G[U]} + \underbrace{\sum_f \bar{\psi}_f M_f \psi_f}_{S_F[\psi, \bar{\psi}, U]} \quad \text{and} \quad Z = \int \mathcal{D}U \mathcal{D}\bar{\psi} \mathcal{D}\psi e^{-S[\psi, \bar{\psi}, U]} \equiv \langle e^{-S} \rangle_{FG}$$

► Fields

► $U_{x,\mu} \approx e^{igaA_\mu(x)}$, $\psi = (\psi_{x_1}, \psi_{x_2}, \dots)$, $x \in \Lambda$

► Fermion matrix with naive μ

► $\hat{H} \rightarrow \hat{H} - \mu \psi^\dagger \psi$

► Dirac $M_f = (\partial_\mu - igA_\mu)\gamma_\mu + m_f - \mu_f \gamma_0$

► Chemical potential as U(1) field:

► $\mu \sim igA_0$, therefore $U_{x,0}^\pm \rightarrow U_{x,0}^\pm e^{\pm\mu a}$,

► “Staggered” (Kogut-Susskind)

► $(M_f)_{x,y} = am_f \delta_{x,y} + \sum_{\nu=1}^4 \frac{\eta_{x,\nu}}{2} \left[e^{+a\mu_f \delta_{\nu,4}} U_{x,\nu} \delta_{x,y-\hat{\nu}} - e^{-a\mu_f \delta_{\nu,4}} U_{x-\hat{\nu},\nu}^\dagger \delta_{x,y+\hat{\nu}} \right]$

► skeleton $M(U, \mu) \sim U_0 e^{\mu a} + U_0^\dagger e^{-\mu a}$

lattice domain

$$\Lambda = a\mathbb{Z}^4 = \{x | \frac{x_\mu}{a} \in \mathbb{Z}\}$$

$$\beta = \int_0^{N\tau a} d\tau = aN\tau = \frac{1}{T}$$

$$V = \int d^3x = (aN_s)^3$$

$$\beta_G = \frac{2N_c}{g^2}$$

Conclusions

$$Z = \int \mathcal{D}U \mathcal{D}\bar{\Psi} \mathcal{D}\Psi e^{\frac{\beta G}{3} \sum_P \text{ReTr}[\Pi_P U] - \bar{\Psi} M \Psi} \quad \Rightarrow \quad Z = \int \mathcal{D}U e^{\frac{\beta G}{3} \sum_P \text{ReTr}[\Pi_P U]} \det M[U]$$

$\int \mathcal{D}\bar{\Psi} \mathcal{D}\Psi e^{-\bar{\Psi} M \Psi} = \det M$

► Probability

$$P[U] = \frac{e^{-S_G[U]} \cdot \det M[U, \mu]}{Z}$$

► with $Z = \int \mathcal{D}U e^{-S_G[U]} \det M(U, \mu) = \langle \det M(U, \mu) \rangle_G$

► Tools

- $\det M = \prod_f \det M_f^{\frac{1}{4}}(U, \mu_f)$ (1/4 root trick)
- Pseudo-fermions: $\det M = \int \mathcal{D}\phi \mathcal{D}\phi^\dagger e^{-\phi^\dagger \frac{1}{M} \phi}$
- Multi-fermions: $\det M = (\det M^{\frac{1}{n}})^n$
- Remez algorithm: $\frac{1}{M^\alpha} = \sum_i \frac{a_i}{M+b_i}$

► RHMC (Rational Hybrid MonteCarlo)

- generate U_i with $P(U_i) \sim e^{-S_G[U_i]} \det M[U_i]$

► calculate $\langle \mathcal{O} \rangle = \frac{1}{N_{conf}} \sum_{i \in conf} O[U_i]$

In summing up:

$$Z = \langle \det M(U, \mu) \rangle_G$$

$$\begin{pmatrix} \bar{\psi}_1 & \bar{\psi}_2 & \cdots \end{pmatrix} \begin{pmatrix} M_{11} & M_{12} & \cdots \\ M_{21} & \ddots & M_{31} \\ \cdots & M_{32} & \ddots \end{pmatrix} \begin{pmatrix} \psi_1 \\ \psi_2 \\ \vdots \end{pmatrix}$$

$i, j = 1 \dots N_\tau N_s^3$

Why complex chemical potential?

$$Z(\mu) = \langle \det [U_0 e^{\mu a} + U_0^+ e^{-\mu a}] \rangle_G$$

- 1) $\det M(U, \mu)^* = \det M(U, -\mu^*)$
- 2) $Z(\mu) = Z(-\mu)$ if $\langle \cdot \rangle_G = \langle \cdot \rangle_{G^*}$
- 3) $Z(\mu)^* = Z(-\mu^*)$

- ▶ Standard Montecarlo unfeasible if $\mu \in \mathcal{R}$ (“sign problem”)

- ▶ $\det M(U, \mu)$ is real only if $\mu^* = -\mu$ (see 1)

- ▶ Way out: Imaginary chemical potential, Taylor expansion, analytic cont., Reweighting at $\mu = 0$, etc

- ▶ Anyway, Nothing is wrong in the QCD formulation at imaginary μ :

- ▶ after averaging on the background gauge fields,

- ▶ $Z(\mu) = \langle \det M(U, \mu) \rangle_G$ is real (see 2,3)

The sign problem

Conclusions

Complex μ : the canonical approach

$$Z(\mu) = \langle \det [U_0 e^{\mu a} + U_0^+ e^{-\mu a}] \rangle_G \quad \text{and} \quad \det M = e^{\text{Tr} \ln M} \underset{aN_\tau = \beta}{\simeq} \left[(\text{Tr} \Pi_\tau U_0^\pm) e^{\pm \beta \mu} \right]_{\square}$$

- ▶ Fugacity expansion (*Laurent expansion* in $\zeta = e^{\beta \mu}$)

$$Z_{GC}(\mu) = \sum_{N=-\infty}^{\infty} (e^{\beta \mu})^N \cdot z_N$$

$$z_N = \oint \frac{d\zeta}{2\pi i} \frac{Z_{GC}(\zeta)}{\zeta^{N+1}} \quad (\text{Cauchy's integral formula})$$

- ▶ Canonical $Z_C(N) \equiv z_N$

$$Z_C(N) = \oint \frac{d(\beta \mu)}{2\pi i} Z_{GC}(\mu) \cdot e^{-(\beta \mu) \cdot N} \quad (\text{Laplace tras.})$$

- ▶ Thermodynamic definitions:

- ▶ $Z_{GC}(\mu) = \text{Tr}[e^{-\beta(\hat{H}_{QCD} - \mu \hat{N})}]$ (“gran canonical”)
- ▶ $Z_C(N) = \text{Tr}[e^{-\beta \hat{H}_{QCD}} \delta(\hat{N} - N)]$ (“canonical”)

Note:

- ▶ $Z_{GC}(\mu)$ and $Z_C(N)$ share the same information (Laplace transforms)

$\beta \mu$ complex plan

Z_3 center symmetry

$$Z = \int \mathcal{D}U \underbrace{e^{\frac{\beta G}{3} \sum_P \text{ReTr}[\prod_P U]}}_{e^{-S_G} = \text{gauge}} \cdot \underbrace{\left(\text{Tr} \prod_{\tau} U_0^{\pm} \right)}_{\det M = \text{fermions}} e^{\pm \beta \mu}$$

Conclusions

- ▶ Center symmetry $U_0 \rightarrow \xi U_0$
 - ▶ $\boxed{\det = 1} \implies \boxed{\xi^{N_c} = 1}$, i.e.
 - $\xi_k = e^{k \frac{2\pi i}{3}} = \{1, \frac{2\pi}{3}i, \frac{4\pi}{3}i\} \in Z_3$
- ▶ The “gauge part” is invariant
 - ▶ $\text{Tr}[\prod_P U] \rightarrow \text{Tr}[\prod_P U]$, $\mathcal{D}U \rightarrow \mathcal{D}U$
- ▶ The “fermion part” explicitly breaks
 - ▶ $P \sim \text{Tr}[\prod_{\tau} U_0]$ (Polyakov loop)
 - ▶ so $P \rightarrow \xi P$
- ▶ Order parameter
 - ▶ $\boxed{\langle P \rangle \neq 0 \implies Z_3 \text{ broken}}$

Polyakov loop $P \sim \text{Tr} \prod U_0$

Note:

1. In the $SU(3)$ pure gauge, $\langle P \rangle \neq 0$ at high temperature, signalling the spontaneous symmetry breakdown of the Z_3 symmetry

RW: the symmetry

$$\det M = e^{\text{Tr} \ln M} \sim \left[\text{Tr} \left(\prod_{\tau} U_0 e^{+\beta \mu} \right) + h.c. \right] \quad \text{and} \quad Z = \langle \det M(U, \mu) \rangle_G$$

- ▶ The Roberge-Weiss symmetry

- ▶ if $U_0 \rightarrow e^{i\frac{2\pi}{3}k} U_0$ and $\beta\mu \rightarrow \beta\mu - i\frac{2\pi}{3}k$

$$\text{▶ } Z(\beta\mu) = Z\left(\beta\mu - i\frac{2\pi}{3}k\right)$$

- ▶ Charge symmetry $\mu \rightarrow -\mu$

- ▶ $Z(\mu) = Z(-\mu)$ is even

- ▶ $\theta' = -\theta + k\frac{2\pi}{3} \implies \frac{\theta' + \theta}{2} = k\frac{\pi}{3}$.

- ▶ Parity+Rotation=Reflection about $\theta = k\frac{\pi}{3}$

- ▶ If $P_{i\pi}(U) = P_{i\pi}(U^*)$

- ▶ RW \sim charge symmetry

$\beta\mu$ complex plane

Z_3 : effect on the spectrum

$$Z_{GC}(\mu) = \sum_{N=-\infty}^{\infty} (e^{\beta\mu})^N \cdot z_N$$

- ▶ **Fact:** if Z_3 is exact:
 - ▶ Under $\xi \in Z_3$, $z_N = \xi^N z_N$ so symmetry implies $z_N = 0$ if $N \bmod 3 \neq 0$
- ▶ **At low temperature:**
 1. Z_3 is exact,
 2. μ periodicity is “smoothly” realized
 - ▶ only $z_0, z_{\pm 3}, z_{\pm 6}, z_{\pm 9}, \dots$ survives
 - ▶ mesons and baryons (\implies *confinement*)
- ▶ **At high temperature:**
 1. Z_3 spontaneously broken,
 2. μ periodicity is realized in non-analytic way
 - ▶ every allowed: $z_0, z_{\pm 1}, z_{\pm 2}, z_{\pm 3} \dots$
 - ▶ + free quarks and antiquarks (\implies *deconfinement*)

Conclusions:

- ▶ Writing $N = 3b + q$, with $q = N \bmod 3$, if Z_3 is exact, only the terms with $q = 0$ survives in the fugacity expansion

$Z_{GC}(\mu) = \sum_b z_{3b} \cdot (e^{3\mu\beta})^b$

 . b is the baryonic number B ; $3\mu = \mu_B$ the baryonic chemical potential

RW: phase transition

Hint, maximize: $\det M \sim \text{Re}(P \cdot e^{\beta\mu}) \sim \text{Ising } \vec{s} \cdot \vec{H}$

► At high T

► $\mu = 0$

► the quark determinant favors the configurations with $\arg P \approx 0$.

► $\mu\beta = \pm i2\pi/3$

► $P \sim (e^{\beta\mu})^* = e^{-\beta\mu} \implies \arg P \sim -\left\{\frac{2\pi}{3}, \frac{4\pi}{3}\right\}$

► P changes abruptly if $\mu\beta \in \{i\pi, -i\pi/3, i\pi/3\}$,

► At low T

► At low temperatures the transition is smooth and we have a **crossover** (dashed lines)

► Order parameter: $|Im(P)|$

- symmetric phase = 0
- broken phase $\neq 0$

P orientation

$$\frac{T(\mu)}{T_c} \approx 1 - b\mu^2 + c\mu^4 \dots$$

The aim of this work

- ▶ Numerical simulations have shown that Roberge-Weiss transition is first order for large masses (*quenched limit*), second order for intermediate masses, and again first order when masses are small (*chiral limit*).

- ▶ The nature of the endpoints is not-trivial and depends on N_f and fermion mass
- ▶ Detailed studies exist only for the cases $N_f = 2$ and $N_f = 2+1$
- ▶ The Gell-mann-Low RG function $\beta(g)$, on which important QCD properties - as the *asymptotic freedom* - are based, depends crucially on the number of flavors N_f . In particular, for N_f larger then $33/2$, the confinement property could change and the phase transition could become weaker or disappear too.

Aim:

- ▶ To extend the simulations to other combinations of masses and flavors, in order to confirm that as a general behavior

Conclusions

Conf:

| N_f | am_q | N_τ | N_s | $\frac{\mu}{T}$ | samples | therm. | jackknife | betastep |
|-------|--------|----------|----------|-----------------|---------|--------|-----------|----------|
| 8 | 0.2 | 4 | 12,16,20 | $i\pi$ | 15000 | 1000 | 300 | 0.001 |

- ▶ Order parameter
 - ▶ $|Im(P)|$
- ▶ Imaginary chemical potential:
 - ▶ $\beta\mu = i\pi$
- ▶ Temperature tuned with the inverse gauge coupling $\beta_G = \frac{6}{g^2}$
 - ▶ (4.940, 4.960, 4.980, 4.985, 4.990, 5.000, 5.020)

SW+HW

- ▶ Zephiro cluster (9 GPU) at INFN Pisa
- ▶ C++ CUDA RHMC

Multi-histogram re-weighting

- $\langle O \rangle = \frac{\sum w \cdot O}{\sum w} = \frac{\sum r \frac{w}{r} \cdot O}{\sum r \frac{w}{r}} = \frac{\langle \frac{w}{r} \cdot O \rangle_r}{\langle \frac{w}{r} \rangle_r}$
- The method is successful, as long there is a good overlapping between the plaquette energy histograms, and especially in the critical region

Jackknife resampling

- accounting correlations
- variance error estimates
- $\tau_{int} = \frac{1}{2} + \sum_{n=0}^{\infty} c(n \cdot \Delta\tau)$
- $N_{eff} \approx \frac{N}{2\tau_{int}}$ (slowing down)

reweighting example

plaquette histogram

Order parameter: Polyakov loop

▶ Polyakov loop

$$P = \frac{1}{V} \sum_{\mathbf{x}} \frac{1}{N_c} \text{Tr}_c \prod_{\tau=0}^{N_\tau-1} U_0(\tau, \mathbf{x})$$

- ▶ Low T: $\langle \text{Im}P \rangle = 0$ (Z_3 restored)
- ▶ High T: $\langle \text{Im}P \rangle \neq 0$ (Z_3 broken)

▶ Polyakov loop susceptibility

$$\chi = V \langle (\delta |\text{Im}(P)|)^2 \rangle$$

- ▶ χ at critical point \Rightarrow peak

Fermionic measures

- Chiral condensate (*left plot*)

$$\langle \bar{\psi} \psi \rangle = -\frac{\partial \ln Z_{GC}}{\partial m} = -\frac{N_f}{N_\tau N_s^3} \langle \text{Tr}[\frac{1}{M}] \rangle_G$$

- high T \implies **chiral sym. restored**

- Quark number (*right plot*)

$$Z(\beta\mu) \text{ is even} \implies \langle N \rangle(\beta\mu) \text{ is odd}$$

$$\langle N \rangle = \frac{\partial \ln Z_{GC}(\beta\mu)}{\partial \beta\mu} = a(\beta\mu) + b(\beta\mu)^3 + \dots$$

- $\langle N \rangle \sim \beta\mu$ **purely imaginary**

Conclusions

Quark number $N = \psi^ \psi$
distribution in the complex plane, at imaginary chemical potential.
 $\langle N \rangle \sim \beta \mu$ is purely imaginary.*

Distribution probability, $|Im(P)|$ 

$$|Im(P)|$$

histogram distribution of the absolute value of the imaginary part of the Polyakov, $N_s = 12$

The figure shows a typical histogram of the distribution probability $P(|Im(P)|)$ across a **second-order transition** (from left to right and top to bottom). The top left graph corresponds to the *ordered phase*, with a single peak at $|Im(P)| = 0$. As the value of T is increased, this peak moves toward to $||Im(P)|| \neq 0$ and no other peak arises.

Finite Size Scaling (FSS)

► Scaling laws:

► $\chi \sim t^{-\gamma}$ and $\xi \sim t^{-\nu}$, $t = (T - T_c)/T_c$ ► $\chi \sim \xi^{\gamma/\nu}$ ► at the pseudo critical point: $\xi_{peak} \sim N_s$ ► so $\chi_{peak} \sim N_s^{\gamma/\nu}$ ► least-square fit $\chi = a \cdot N_s^b$, to find $b = \gamma/\nu$.

Result: $\gamma/\nu = 1.9 \pm 0.3$, compatible with $\gamma/\nu = 1.964$, corresponding to the 3D Ising universal class (a **second order transition**)

Binder cumulant B_4

► $B_4 = \frac{\langle \delta x^4 \rangle}{(\langle \delta x^2 \rangle)^2}$ with $x = |Im(P)|$

- $B_4 = 3$ single gaussian (*symmetric phase*)
- $B_4 = 1$ double gaussian (*crossover*)

The B_4 , at various N_s , should cross at the pseudo-critical point

Collapse plot ($|Im(P)|$)

▶ $\chi \sim N_s^{\gamma/\nu} f((\beta - \beta_{RW}) \cdot N_s^{1/\nu})$ with $f(x)$ universal function

- ▶ on the left (1th order: $\gamma = 1, \nu = 1/3$)
- ▶ on the right (2th order 3D Ising: $\gamma = 1.2372, \nu = 0.63$)

Better overlapping for 2th order, $\beta_{RW} = 4.986$

Collapse plot: zoom

Conclusions

► ZOOM

- ▶ on the left (1th order: $\gamma = 1, \nu = 1/3$)
- ▶ on the right (2th order 3D Ising: $\gamma = 1.2372, \nu = 0.63$)

Better overlapping for 2th order, $\beta_{RW} = 4.986$

Conclusions and outlook

- ▶ We have presented the case $N_f = 8$ with $am_q = 0.2$ and imaginary chemical potential $\mu = i\pi T$ (Roberge-Weiss line)
- ▶ The result show that, for $am_q = 0.2$, the endpoint for $N_f = 8$ and $N_f = 4$ is still 2th order, so $m_{t1} < m_q < m_{t2}$

| NF | m | β_{RW} | order |
|----|----------|--------------|-------|
| 4 | $m=0.09$ | 5.175 | 1th |
| 4 | $m=0.20$ | 5.310 | 2th |
| 4 | $m=0.50$ | 5.497 | 2th |
| 8 | $m=0.20$ | 4.987 | 2th |

Next:

- ▶ To complete the case $N_f = 8$ for other masses, with a new estimate for $m_1(N_f)$ and $m_2(N_f)$.
- ▶ To explore higher values for N_f (for example: the region $N_f > 33/2$)

Thank You for the attention!
